

statsmodels.tsa.seasonal.seasonal_decompose

`statsmodels.tsa.seasonal.seasonal_decompose(x, model='additive', filt=None, period=None, two_sided=True, extrapolate_trend=0)`[\[source\]](#)
[../_modules/statsmodels/tsa/seasonal.html#seasonal_decompose]

Seasonal decomposition using moving averages.

Parameters:

x : [array_like](#) [\[https://numpy.org/doc/stable/glossary.html#term-array_like\]](https://numpy.org/doc/stable/glossary.html#term-array_like)

Time series. If 2d, individual series are in columns. x must contain 2 complete cycles.

model : {"additive", "multiplicative"}, **optional**

Type of seasonal component. Abbreviations are accepted.

filt : [array_like](#) [\[https://numpy.org/doc/stable/glossary.html#term-array_like\]](https://numpy.org/doc/stable/glossary.html#term-array_like), **optional**

The filter coefficients for filtering out the seasonal component. The concrete moving average method used in filtering is determined by `two_sided`.

period : [int](#) [\[https://docs.python.org/3/library/functions.html#int\]](https://docs.python.org/3/library/functions.html#int), **optional**

Period of the series. Must be used if x is not a pandas object or if the index of x does not have a frequency. Overrides default periodicity of x if x is a pandas object with a timeseries index.

two_sided : [bool](#) [\[https://docs.python.org/3/library/stdtypes.html#builtin-boolean-values\]](https://docs.python.org/3/library/stdtypes.html#builtin-boolean-values), **optional**

The moving average method used in filtering. If True (default), a centered moving average is computed using the `filt`. If False, the filter coefficients are for past values only.

extrapolate_trend : [int](#) [\[https://docs.python.org/3/library/functions.html#int\]](https://docs.python.org/3/library/functions.html#int) or 'freq', **optional**

If set to > 0, the trend resulting from the convolution is linear least-squares extrapolated on both ends (or the single one if `two_sided` is False) considering this many (+1) closest points. If set to 'freq', use *freq* closest points. Setting this parameter results in no NaN values in trend or resid components.

Returns:

[DecomposeResult](#) [\[statsmodels.tsa.seasonal.DecomposeResult.html#statsmodels.tsa.seasonal.DecomposeResult\]](statsmodels.tsa.seasonal.DecomposeResult.html#statsmodels.tsa.seasonal.DecomposeResult)

A object with seasonal, trend, and resid attributes.

Season-Trend decomposition using LOESS.

Notes

This is a naive decomposition. More sophisticated methods should be preferred.

The additive model is $Y[t] = T[t] + S[t] + e[t]$

The multiplicative model is $Y[t] = T[t] * S[t] * e[t]$

The results are obtained by first estimating the trend by applying a convolution filter to the data. The trend is then removed from the series and the average of this de-trended series for each period is the returned seasonal component.
